

ABSTRACT

5 A process for producing an ethylene-vinyl alcohol copolymer resin,
including feeding EVOH into an extruder, keeping the temperature of the
melting resin in the extruder at 70 to 170°C, adjusting the amount of water in
the extruder so that the water content right after being discharged from the
extruder is 5 to 40 weight %, and extruding out the EVOH resin. The
extruded EVOH resin is cut into EVOH pellets. Thereby, it is possible to
10 obtain resin pellets in which no spherocrystals are observed in the center of
the cross section of the resin when the cross section is observed by the use of a
polarization microscope, or no lubricant is contained in the resin pellets, and
the angle of repose is 23 ° or less when the resin pellets are laminated.
Thus, it is possible to provide an ethylene-vinyl alcohol copolymer (EVOH)
resin pellet having a reduced discharging load to the environment and capable
15 of being fed into an extruder smoothly without being blocked, extruding
stability, and thermal stability (long-run property).
